AUTHOR: Mikhaylov, O.A. (Cand.Tech.Sci.) 133-8-9/28

TITLE: All-Union Conference of Steelmakers. (Vsesoyuznoye soveshchaniye staleplavil'shchikov).

PERIODICAL: "Stal'" (Steel), No.8, 1957, pp.715-717 (USSR).

ABSTRACT: The conference took place in May in Sverdlovsk. 800 representatives from all branches of steel making participated in the conference. Only the introductory paper by A.F. Myrtsov, Head of the Technical Board of the Ministry of Iron and Steel Metallurgy is reported in some detail. Main points were: steel production in 1956 was 48.6 million tons; 90% of which was produced in open hearth furnaces. 52% of the output came from furnaces of a capacity of 200 ton and above. The best productivity of 34 tons/hr was obtained by furnaces of 370 t. capacity. The proportion of furnaces with chromemagnesite roofs increased to: open hearth furnaces 79%; electric arc furnaces - 49%. The productivity of labour during the last two years increased by about 18%. The remaining part of the proceedings is described in general terms. The conference voiced criticism of design institutes and organisations (Gipromez, Stal'proyek, Special Design Office of "Elektropech", etc.) and the Ministry of the Iron and Steel Metallurgy, pointing out that many of the decisions of the previous conference

Card 1/2

All-Union Conference of Steelmakers. (Cont.) 133-8-9/28
were not fulfilled. The main points of the conference's resolutions were: design of a 700 ton open hearth furnace and a melting shop with such furnaces; the construction of an industrial installation for continuous casting from ladles of 130 t capacity on the Stalinskiy Metallurgical Works; studies of purification of waste gas from steel making furnaces in order to recommend the best systems; speed up the design of vacuum high frequency and arc furnaces with a vacuum of 10^{-3} - 10^{-4} mm Hg, for smelting heat resistant steels; laboratory investigations of the influence of vacuum of 10^{-6} mmHg for smelting special steels. The conference proceedings were closed by a summary given by V.S.Bychkov, Deputy Minister of the Iron and Steel Metallurgy and Chairman of the Scientific-Technical Society of the Iron and Steel Industry, who stressed the importance of the organisation of the management side of the industry.

Translation from Referativnyy zhurnal, Metallurgiya, 1958, Nr 6, p 81 (USSR)

AUTHOR Mikhaylov, O.A.

TITLE: The Electric Steel Industry Abroad (Elektrostaleplavil'noye proizvodstvo za rubezhom)

PERIODICAL: Tr. Nauchno-tekhn. o-va chernoy metallurgii, 1957, Vol 18, pp 679-693

ABSTRACT Data are adduced on the development of the electric steel industry in the capitalist countries, on the dimensions and performance criteria of electric furnaces (F), note being taken of the increase in annual capacities of F to 10,200,000 t in the USA in 1956. Progress in arc-F design is along the lines of conversion to top charging with predominance of the swing-roof type, increase in F shell height and in the diameter of roof rings so as to remove them from the high-temperature zone, development of devices to remove gases and trap F dust, increase in transformer power, increase in secondary voltage and development of new designs of electrode controls, particularly of the electrohydraulic and electromechanical types.

The Electric Steel Industry Abroad

containing 60% Al₂O₃, fused magnesite chrome brick, and chromite for ramming hearths, is described. Special features of the smelting of stainless steels with ~0.03% C in F are examined, as are questions dealing with induction stirring of the metal in F, smelting rare-earth-element (Ce and La) steels, steelmaking in vacuum induction furnaces and the use of vacuum in the pouring of steel.

TITLE: Wave method for calculating impulse loading of turbine blades

SOURCE: Sudostroyeniye, no. 11, 1964, 33-34

TOPIC TAGS: turbine blade vibration, turbine blade stress, impulsive loading

ABSTRACT: The wave method for calculating impulse loading of turbine blades is discussed. During impulse loading, when such factors as shear and section inertia have to be considered, the normal differential equation of bending of the elastic line is insufficient, and the wave equation derived by Timoshenko and applied by A. Petrov (Deformatsii tsilindricheskikh lopatok turbomashin pri impul'snykh agruzkakh, Trudy LKI, vy^zp. XIII, 1964) has to be used. The effects of temperature, partial admission, damping, stiffness, time of loading and unloading, et cetera on the characteristics of the wave are thus considered. The solution can be obtained in terms of a definite integral, a series of free vibration shapes for finding the bending moment), or as a finite sum of primary and reflected waves (for finding shear forces). A solution of the nondimensional wave equation

TITLE: Wave-method investigation of impulse deformations of turbomachine
blades

SOURCE: Energomashinostroyeniye, no. 7, 1964, 19-22

TOPIC TAGS: turbine, turbine blade, turbine blade test, turbine blade vibration,
turbine blade stress

ABSTRACT: A theoretical and experimental investigation of turbine-blade
impulse stress is reported. By solving the well-known Timoshenko beam
equations by the operational method, the shearing force in a blade, which vibrates
as the result of an impact, is found. Also, a formula for the frequency of
vibration is developed. The theory was verified on an experimental outfit (see

1/3

CESSION NR: AP4042862

g 2, Enclosure 1) which included bar 1 striking against the tip of the blade whose hub end was fixed in vise 3. Tensometers and associated electronic equipment permitted recording the blade vibration (see Fig 3, Enclosure 1); oscillograms 1, 2, 3 represent blade deformations at 23, 74, and 125 mm from the tip. From this data, stresses due to propagating bending and shearing waves and max shearing force can be determined. Orig. art. has: 3 figures and formulas.

SOV/3450

Termicheskaya obrabotka i svoystva krupnykh pokovok (Heat Treatment and Properties of Large Forgings), Moscow, Mashgiz, 1959. 165 p. 4,000 copies printed.

Reviewer: K.N. Sokolov, Candidate of Technical Sciences; Ed.: P.V. Sklyuyev, Candidate of Technical Sciences; Tech. Ed.: N.A. Dugina; Exec. Ed. (Ural-Siberian Division, Mashgiz): A.V. Kaletina, Engineer.

PURPOSE: This book is intended for technical personnel working in the shops, laboratories, and design offices of plants manufacturing heavy machinery and electrical equipment. It may also be of some interest to research personnel.

COVERAGE: This collection of articles describes methods employed by Uralmashzavod (Ural Heavy Machinery Plant, Sverdlovsk) for heat-treating heavy forgings. Research conducted at the plant is also discussed. Data for computing cooling rates in the quenching and normalizing of heavy forgings are given. A considerable portion of the book is devoted to information on the mechanical properties of rotors for heavy turbogenerators and one-piece steam-turbine rotors at various points along the body and neck of these parts. The main defects occurring in rotors of these types are described, their causes

Card 1/5

Heat Treatment and Properties of Large forgings 80V/3450

are analyzed, and methods of handling the problem are explained. Results of a study of heavy forgings made of vacuum-treated steel are given. No personalities are mentioned. References accompany most of the articles.

AUTHOR: Mikhaylov, O. N., Candidate of Technical Sciences

TITLE: Calculating the Resonant Frequency of Vibration of Bundles of Blades of Steam Turbines

PERIODICAL: Energomashinostroyeniye, 1960, No. 8, pp. 22-26

TEXT: A. V. Levin and U. Ye. Rivosh, in books on the subject, have given a convenient method of calculating the natural frequency of vibration of bundles of blades of various sections, based on energy principles. The calculation consists in determining the bending of the blades in the bundle, according to the diagram shown in Fig. 1a. This gives a statically indeterminate system, which is solved by the method of forces. The main system is shown in Fig. 1b. Bending of the free blades and additional bending due to the action of the lacing wires are determined separately by integration. The method is widely used in practice, though it is difficult to apply. The calculation is more compact if the strain method is taken as the main system as was done by I. M. Rabinovich and S. A. Rogitskiy in their books. In this case a clamp is temporarily introduced at the

X

Calculating the Resonant Frequency of Vibration of Bundles of Blades of Steam Turbines

place of fixing of the lacing wires. Then the calculation may be continued by the strain method or by the method of distribution of the clamping torques. This latter is examined further as it avoids solution of a system of canonical equations. The actual bending of blades in the bundle is obtained not by summatting elementary bendings but by tabulated integration of the total diagram of moments, so that many intermediate operations are obviated. Though the diagram of moments is not a continuous function, its discontinuities may be integrated and in the table of integration it may be considered as continuous. The essentials of the method are considered in more detail. The first variant of the method for calculating a statically indeterminate system by the method of distribution of clamping moment is considered. It involves knowing the moments acting on the clamp from adjacent sections of the system due to turning the clamp through an angle and also due to the application of a load. These moments are readily calculated for a bar of a instant section with simple

Calculating the Resonant Frequency of Vibration of Bundles of
Blades of Steam Turbines

loading. For the case of blades of varying section, the problem is simplified by supposing that the moments of inertia of cross sections of the blades between lacing wires vary according to a linear law. Then determination of the moments of distribution and the moments of clamping may be reduced to formulae which are valid for the bar of constant section with correction factors. The mathematics of this procedure are given. The relative energy of the vibrating blades is then determined by finding the diagram of effective moments and the results are tabulated. The method of determining bending of the blades at places where the wires are fixed is explained. The natural frequency of the first type of oscillation of the bundle of blades is then calculated, the result obtained is within 1.5% of that calculated by Levin's method. The difference arises mainly from the assumption of linear change of moments of inertia between connecting points and partly from the fact that the blade is divided into a smaller number of sections than Levin used. The method of calculation

Card 3/5

Calculating the Resonant Frequency of Vibration of Bundles of
Blades of Steam Turbines

described shows the various kinds of action clearly but it cannot be used for bundles of blades with complex loading, for instance, with loading due to inertia forces. In such cases the clamping moments may be determined by tabulated integration. The moments of distribution may be determined in a similar manner, and there is no need to make any assumption about the linear change of moments of inertia used above. The principles of making the calculations are explained by a worked example. This second variant of the method of calculation may also be used to determine the resonant frequency of the second type for a bundle of blades. The main principles are explained; the calculation is generally analogous with the calculation of dynamic stresses for vibrations of the first type. By dividing the blade up into ten sections a result may be obtained which differs by only 2% from that obtained by Levin, who divided the blade up into twenty sections. An editorial note is appended which allows that the method proposed by the author can be used to calculate the natural frequency of

Calculating the Resonant Frequency of Vibration of Bundles of Blades of Steam Turbines

the first and second modes of vibration of bundles of turbine blades with various methods of loading without great difficulty. In the editor's opinion, the accuracy of the results cannot always satisfy the designer. However, it is thus difficult to agree with the author that his method of calculation is an improvement on the usual energy principle and the force method which is at the basis of the procedure of Levin and Rivesh. There are 3 figures, 6 tables and 5 Soviet references

sounder, UNDERWATER ACOUSTICS

TRACT: The processing of the observational data has shown that seasonal varia-
tions of the hydrological regime in the Mediterranean and Black Seas introduces
significant deviations in the mean values of vertical sound velocities. To correct
this obtained by echo-sounders in the Mediterranean and Black Seas, standard
generalized diagrams of corrections are suggested that can be applied to correcting
depths from 100 m in the Black Sea and from 150 m in the Mediterranean Sea down to
minimum depths. Orig. art. has: 3 tables.

"Effect of the Atomic Weapon on Airfields," by Engineer-Lt Col
P. Mikhaylov, Candidate of Technical Sciences, Sovetskaya Aviat-
siya, 16 Jan 57

The author discusses, on the basis of "data recently published in the foreign press," the destructive effects of atomic weapons, including air explosions, underground explosions, and surface explosions, on airfields and air bases. Both blast and radiation effects on equipment, personnel, and structures are discussed.

The author concludes with the statement that "... by taking appropriate defensive measures the above-mentioned damage to airfields can be significantly reduced or entirely prevented. Today's airfields, as a rule, are provided with suitable antiair defense, engineering structures, and also supersonic fighters and ground-to-air guided missiles. All of this will significantly reduce the possibility of atomic strikes against airfields."

AUTHOR: Mikhaylov, P., Pilot First Class, Hero of the Soviet Union

TITLE: Moskva (Subtitle: New Planes [Novyye samolety])

PERIODICAL: Grazhdanskaya Aviatsiya, 1957, Nr 8, pp. 10-13 (USSR)

ABSTRACT: The new turboprop aircraft "Moskva" was designed by S. V. Il'yushin. The industry will turn out the plane in two types for 75 and 100 passengers. The 75-passenger type was recently demonstrated at Vnukovo; the article discusses mainly this type. The aircraft "Moskva" is a low-wing monoplane equipped with four engines. The plane can fly safely at an altitude of 8,000 meters with a speed of 650 km per hour. The fuselage has a monocoque structure and consists of two sections. The main section, hermetically separated from the rest, is 28 meters in length: it contains the cockpit, all passenger and service (buffet, toilet) compartments and the largest portion of the cargo and storage facilities. The seats for the crew and the passengers are shown on the accompanying diagrams.

Card 1/5

84-8-9, 36

Moskva (Cont.)

The two luggage compartments on the bottom of the fuselage have a capacity of 28 cubic meters. The main section of the fuselage is divided by light partitions. The sector behind the cockpit is 2.95 meters in length and comprises the luggage and toilet rooms for the crew and the front entrance. Through this entrance one reaches the other two compartments, i.e. the first passenger cabin for 10 and the kitchen-buffet room. The central portion of the fuselage is the main passenger cabin for 65 people. The height of the passenger cabin is 2 meters above the gangway; the width of the gangway is 500 mm; the diameter of windows is 40 cm. The illumination is from the ceiling, and the cabins are air conditioned and pressurized. Up to 8,000 meters the air pressure corresponds to an altitude of 1,500 meters, at 10,000 meters to 2,400 meters. Behind the main passenger cabin (in the rear of the plane) is the cloakroom, two toilets, and the main entrance. The tail compartment, with a capacity of 7 cubic meters, is not pressurized. The span of the wing is 37.4 meters. The wing consists of center section and two outer panels. The wing center section has a length of 22 meters, and carries the fuselage,

Card 2/5

84-8-9/36

Moskva (Cont.)

4 engine nacelles and the main landing gear. All-metal ailerons have a full weight balance and aerodynamic compensation; they are set up on the outboard panels. The landing gear is of a tricycle type; the two main legs carry four-wheel bogies equipped with pneumatic wheels. The retraction is hydraulic. The four turboprop engines are of the HK-4 type, designed by N. D. Kuznetsov, with a take-off power of 4,000 equivalent hp each. The engines have four-blade reversible propellers with blade roots provided with ball bearings. The propellers are of the constant-speed variable pitch-type with automatic feathering. The propellers can also be controlled electrically and mechanically. The oil tank has a capacity of 38 liters and is equipped with all necessary pumping accessories. Fuel tanks are symmetrically placed in the wing, feeding separately the left and the right group of engines. The plane can fly 2,000 km with a load of 14 tons without refuelling; with less load it can fly up to 5,000 km. Take-off weight is 58 tons, structural weight is 28 tons. The hydraulic system of the plane has a working pressure

Card 3/5

84-8-9/36

Moskva (Cont.)

of 210 kg per square cm, comprising retraction mechanism, brakes, steering and windshields (except for the emergency braking mechanism which is accomplished by air). Anti-icing of the wing, tail, and propeller is done thermoelectrically, using 6 to 14 kw per 1 square meter. The system switches off automatically in case of overheating. The electric power plant produces dc and ac current; the total capacity is up to 130 kw. Direct current is produced by four pairs of generators attached to each engine. Single-phase generators for 115 volts produce 400-cycle current. In addition, the plane is equipped with powerful storage batteries. The plane can take-off by using only three engines and fly by using two only of its four engines. V. K. Kokkinaki, testing pilot, Hero of the Soviet Union, praised the stability of the aircraft. Numerous navigation instruments, including course and glide path indicators and radar, allow flying by night, as well as under difficult meteorological conditions. The ton per km cost is the lowest in the world. The plane has good take-off capabilities and a short landing run, i.e. 700 to 750 meters in the first case and 500 to 600 in the second. While landing, the plane is not sensitive to cross winds. Four photographs and five

Card 4/5

Moskva (Cont.)

84-8-9/36

diagrams accompany the article. The photograph on page 10 shows three men standing in front of the "Moskva". Caption reads: Leading testing pilot of "Moskva" comrade V. K. Kokkinaki, Hero of the Soviet Union, comrade S. V. Il'yushin, chief aircraft constructor, and comrade V. N. Bugayevskiy, assistant to the chief constructor of the OKB. Photo on page 11 shows inside view of the passenger compartment in the "Moskva". Photo on page 12 (top) shows the "Moskva" after landing. The photo was made by P. Balabanov. Another photo on page 12 (bottom) shows pilots V. K. Kokkinaki and E. I. Kuznetsov in the cockpit of the "Moskva". The five diagrams on page 11 show the "Moskva" aircraft from the front, from the top, from the side; and two supplemental views of the plane (vertically and horizontally).

PURPOSE: This book is intended for the general reader.

CONTENTS: The papers in this collection discuss in popular style, and on the basis of data published in the Soviet and non-Soviet press, the problems of the use of atomic and hydrogen weapons in combat operations at sea. The collection includes reports on the damage factors of nuclear explosion and on the use power of this weapon of mass destruction of ships and on the introduction of antiaircraft defense of a number of articles are devoted to the introduction of nuclear power plants in naval vessels, and to the collection are papers dealing with the future prospects for naval use of nuclear energy, and with the construction of the world's first atomic icebreaker, the "Soviet," which is expected to play an important part in the further conquest of the Arctic regions. The collection also contains papers published in the journal "Soviet Navy" from 1955 - 1959, is revised and supplemented form.

PHASE I BOOK EXPLOITATION

SOV/6261

Kernenergie und Flotte; Artikelsammlung (Nuclear Energy and the Navy; Collection of Articles) [Berlin] Deutscher Militärverlag [1961]. 232 p. Errata slip inserted. 2000 copies printed.

Translation from the Russian of: Atomnaya energiya i flot.

Translator: Erika Stouk, Lieutenant Commander. Responsibility for German edition: Claus Gruszka, Engineer; Ed.: Klaus Krumsiek.

PURPOSE: This collection of articles is intended for officers of the army, coast guard, and merchant marine.

COVERAGE: The book, a translation from the Russian, contains 25 articles dealing with the application of nuclear weapons to naval combat operations. Chapters 19 and 25 have been supplemented with additional data for this edition. The devastating features of nuclear explosions are discussed. Attention is also given to the protection of personnel, ships, and coastal facilities against nuclear weapons, and to the present and future applications of nuclear power plants to shipping. No personalities are mentioned. There are 16 references: 10 Russian (including 3 translations from English-language sources), 1 French, 1 German, 1 English, 1 American, and 2 either English or American.

TITLE: A Machine for Fatigue Testing of Metal Under Pulsating Tensile or Compressive Stresses (Mashina dlya ispytaniya metalla na ustalost' pri pul'siruyushchem rastyazhenii ili szhatii)

PERIODICAL: Nauch. zap. In-ta mashinoved. i avtomatiki AN UkrSSR. Vol 3. Voprosy mashinovedeniya i prochnosti v mashinostroyenii, 1954. Nr 2, pp 100-110

ABSTRACT: A description of an inertia-type machine for testing of specimens immersed in various liquid media and subjected to pulsating tensile or compressive stresses. The loads acting on the specimens or components are measured with the aid of electrical strain gages. Owing to the employment of these gages, which permit measuring the stresses directly on the specimen, the fatigue limit may be determined with a high degree of accuracy. The calibration of the gages is also accomplished in their operating position. The device may also be employed without the electrical strain gages, in which case the cyclic loading is determined by calculation.

TITLE: Experimental Data on the Anti-Friction Properties of
Kapron Tape ^{1971/1972/1973/1974} Elektrosvitovye funktsii v
antifriksionnykh svyazivaniyah.

PERIODICAL: Vestnik Mashinostroyeniya, 1973, No 2, pp 31-36 (USSR)

ABSTRACT: Tests were made on simulated bearings with strips of
kapron supporting a steel shaft 10 mm diameter. Rubbing
speed varied from 0.417 to 1.1 metres/sec under bearing
pressures of 30 to 150 kg/cm². Fig 1 shows turning
moment versus total frictional load at different loads at
a constant rubbing speed of 0.727 m/sec. Fig 2 shows
coefficient of friction against bearing pressure. In
both cases the bearing was lubricated with machine oil.
Fig 3 shows the same but without circulation of oil
i.e. without cooling. Fig 4 shows the relation between
friction and rubbing speed using an anti-friction
Fig 5 shows friction versus bearing pressure and rubbing
speed for polyamide specimens containing 1 to 2% of
"silver graphite", again lubricated with an anti-
lubricant. The authors conclusions are: 1) 2% parts

Card 1/3

...UV/122-59-2-11/34

Experimental Data on the Anti-Friction Properties of Caprone

can work satisfactorily under moist conditions since their swelling on water absorption is negligible. Caprone parts do not absorb mineral oil and cannot dry-out and are consequently more suitable than leather or oil-resistant rubber for hydraulic packings. Caprone liners and sleeves can be used for anti-friction parts with thick or with liquid lubricants. The coefficient of friction against steel using liquid lubricant without cooling is little different from the coefficient of friction of a bronze bearing and the wear coefficient of caprone is 10 to 100 times less than with lubricated bronze and steel friction pairs. Under conditions of reduced lubrication caprone bearings should have graphite added but, with sufficient lubrication, graphited caprone is not advantageous. The cost of caprone parts per unit volume is 6 times less than the cost of the cheapest bronze parts. Caprone sleeves and liners can be used instead of "Textonite" and laminated wood for lubricated

TITLE: The Antifriction Properties of Caprone

PERIODICAL: Plasticheskiye massy, 1960, N. 4, pp. 38-41

TEXT: The authors report on their studies of the physico-mechanical and antifriction properties of caprone in the Laboratory "Detali mashin" (Machine Parts) of the Zaporozhskiy mashin stroitel'nyy institut (Zaporozh'ye Machine Construction Institute) in cooperation with plants of the Zaporozhskiy sovnarkhoz (Zaporozh'ye Council of National Economy). The dependence of the friction coefficient on the specific pressure, rubbing speed, type of lubricant, and manufacturing method of the caprone parts was studied. A specially redesigned "MM" ("MI") machine was used for this purpose. The following caprone samples were studied: 1) large samples from the Zaporozhskiy zavod "Kommunar" (Zaporozh'ye "Kommunar" Plant); 2) samples molten in an autoclave; and 3) samples produced with the extruder press designed by the authors. Moreover, samples were studied which contained graphite, aluminum, and bronze powders, as well as metal samples

covered by a caprone layer 0.1 to 0.3 mm thick. The authors drew the following conclusions on the basis of their results: 1) Caprone may be used for bearings with lubricants of low and high viscosity. The friction coefficient of caprone on steel with lubricants of low viscosity and without cooling differs only slightly from that of bronze. The wear of a caprone bearing and a steel shaft operating with lubricants is very low compared to the wear of a bronze bearing and a steel shaft. 2) The use of caprone with graphite addition is recommended for friction with sparse lubrication. 3) The loading capacity of metal bearings with caprone coating is much higher than that of pure caprone bearings. 4) Caprone bearings operate satisfactorily at a lubricating-oil temperature of up to 80-85°C. 5) The antifriction properties of caprone depend on its manufacturing method. The friction coefficient and wear of caprone samples made with an extruder press are lower than those of samples produced by other means. 6) The anti-friction properties of caprone are impaired by normalizing in boiling water. 7) The addition of aluminum and bronze powders reduces the shrinkage of caprone parts, increases their thermal conductivity, but does not improve their antifriction properties. 8) Special attention should be paid to structural changes of caprone during normalizing. The authors suggest

TITLE: On the antifriction properties of caprone

PERIODICAL: Referativnyy zhurnal. Metalloobrabotka, n. 6, 1982, 2c, abstract
6A16 (V sib. "Plastmassy v mashinostr. i priboirostr.", Kiyev,
S. stekhizmat UkrSSR, 1981, 34, -73)

TEXT: The authors determined the magnitude of the friction coefficient depending on the load ($P = 10$ kg/cm 2), sliding speed ($v = 0.5 - 2.0$ m/sec), type of lubricant, manufacturing technology of the caprone specimens (pressing on worm presses, in casting machines and in autoclaves) during caprone friction on steel. It was found that the wear of caprone on steel shafts in operation with lubricants was less than the wear of bronze on steel shafts. Caprone bearings can operate at lubrication temperatures of $\delta t = 85^\circ\text{C}$. Under conditions of poor lubrication it is recommended to use caprone with graphite. The normalization of caprone in boiling water deteriorates its antifriction properties. If aluminum and bronze powders are added to caprone, its heat conductivity is increased but its antifriction properties are not improved.

TEXT: The screw press described here is superior to other such presses because the high turning speed of its screw minimizes the thermal destruction of the material and insures a uniform temperature distribution in the melt. The high-speed screw press works well when the material is heated by its own friction. The application of vacuum to the melt during its transport by the screw decreases sharply its content of low-molecular weight fractions and allows

TITLE: Corrosion resistance and fatigue strength of ShKh15 steel after electroslag
smelting

SOURCE: AN UkrRSR. Instytut mashynoznavstva i avtomatyky, Lviv. Vliyanije
rabochikh sred na svoystva materialov (Effect of active media on the properties of
materials), no. 2, 1963, 67-76

TOPIC TAGS: electroslag steel, electroslag remelting, steel ShKh15, steel corrosion
resistance, steel fatigue strength, corrosion, corrosion resistance

ABSTRACT: The Institut elektrosvarki im. Ye. O. Patona AN USSR (Institute of
Electric Welding) has developed a method of electroslag smelting which is now in wide
use to decrease the number of nonmetallic inclusions and thus increase the corrosion
resistance of steel. The purpose of the present paper was to determine the effect of re-
smelting on contamination of ShKh15 steel with oxides, sulfides, and air bubbles and the
corrosion resistance and corrosion-fatigue strength of this steel, in both the perlite-
ferrite and martensite states, in 3% sodium chloride. The results showed that electroslag

rd 1/3

ACCESSION NR: AT4023777

Smelting of ShKh15 steel in the ZMI machine decreased the content of impurities by 2-2.5 units and the porosity at the center by 0.5 units. As shown in the Enclosure, smelting increased corrosion resistance by up to 15% in 3% sodium chloride, but increased it only insignificantly in air. Smelting increased the corrosion-fatigue strength of ShKh15 steel by up to 40% in the martensitic hardened condition and by up to 20% before hardening. However, lowering the quantity of impurities below a certain value did not affect the corrosion and corrosion-fatigue strength of the steel. "The thermal treatment was carried out by F. P. Yanchishin (Cand. Tech. Sci.) and Eng. K. P. Tabinskiy." Orig. art. has: 4 figures, 4 tables and 3 formulas.
